## Valor Discovers High Grade Copper & Silver Mineralisation at Surface in New Project Area, "Corona"

Valor Resources Limited ("VAL" or the "Company") is very pleased to report the first results of the previously announced surface sampling campaign. VAL has identified significant high grade mineralisation at surface, approximately 1,500 metres southwest of Berenguela Central, within the Berenguela concession package, in an area called 'Corona'.

### Highlights:

- This discovery indicates a possible significant extension to the existing Berenguela central deposit.
- VAL's Corona sampling campaign confirms extensive "Berenguela-style" mineralisation at surface across a substantial area, similar in size to Berenguela Central.
- Drill permitting for Corona target is underway.
- Further sampling results for Berenguela Central pending release in the coming days.

### Corona Sampling Highlights:

Cu (%)	Ag (g/t)
2.79	431
1.69	78.48
1.37	55.60
1.19	72.40
0.81	61.50
0.63	124

### Management Commentary

Valor Chairman, Mark Sumner said: "The high-grade copper and silver mineralisation encountered within the Corona area is indicative of further Berenguela-style, near-surface, mineralisation, less than 1,500 metres from the Central deposit area. The outcropping mineralisation at Corona is very similar to the surface outcrops previously identified at Berenguela Central, so we believe that this is an opportunity to add a completely new deposit to the project within close proximity to Berenguela. We believe Corona has the potential to add significant resources to the Berenguela project and it is a very valuable discovery."

## Management Commentary continued:

*"We have always maintained that we have only scratched the surface at Berenguela and the mineralisation tested at Corona is clear evidence of this. Corona was discovered by utilising both historical exploration results, as well as a simple and inexpensive surface sampling and field mapping exercise. We will continue with more detailed field mapping of the Corona area, so we are fully prepared to test Corona in the next drilling program.*

*We have sample results pending from the Berenguela central area also, which will give us an idea of the potential for further at surface, high grade mineralisation. We expect to announce the central results a week from now.*

*Corona is a very exciting development for Valor. Since May 2017, we have increased resources at Berenguela by 80%, more than doubling contained copper and increasing contained silver resources to over 127 million ounces. We expect Corona to contribute significantly to the value of the Berenguela project in the coming months."*

**Sampling Mineralisation at Surface in Corona Area**

## Sampling Program Overview:

The recent sampling campaign was designed to confirm the extension of the Berenguela Central deposit along the northern, southern and western borders. Sample locations were selected to both confirm and expand drill targets for the planned 2018 drill program. A total of 85 rock chip samples were taken across Berenguela Central and Corona to confirm mineralisation associated with manganese oxide mantles and veins. All samples were shipped to SGS labs in Lima for assay. The results of the program confirmed mineralised significant surface mineralisation at Corona.

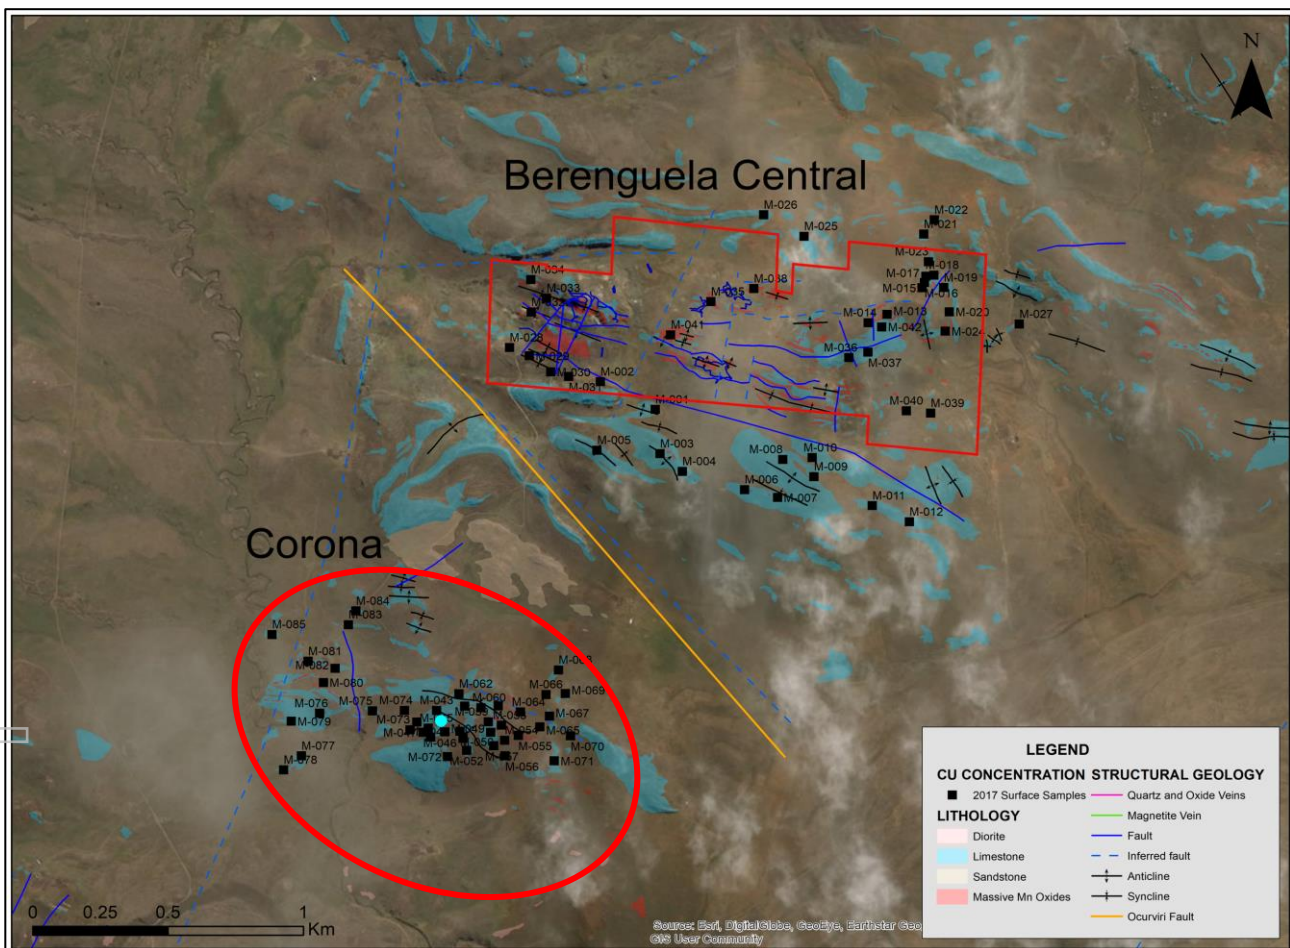

## Geologic Setting

The Berenguela property now consists of two mineralized zones, Berenguela Central and Corona. The central deposit is bounded on the west by a northwest-southeast trending fault, this orientation is very typical for structural features in Peru. The Ocurviri Fault is the major fault that separates older

Mesozoic and Paleozoic rocks from the younger Tertiary Tacaza Group. The Tacaza Group hosts most of the mineralisation at Berenguela Central and the Corona area is located within limestones of the Tacaza Group. The presence of the fault separating the central deposit from the Corona deposit allows for a larger diversity of mineralisation.

### Corona Overview & Dimensions

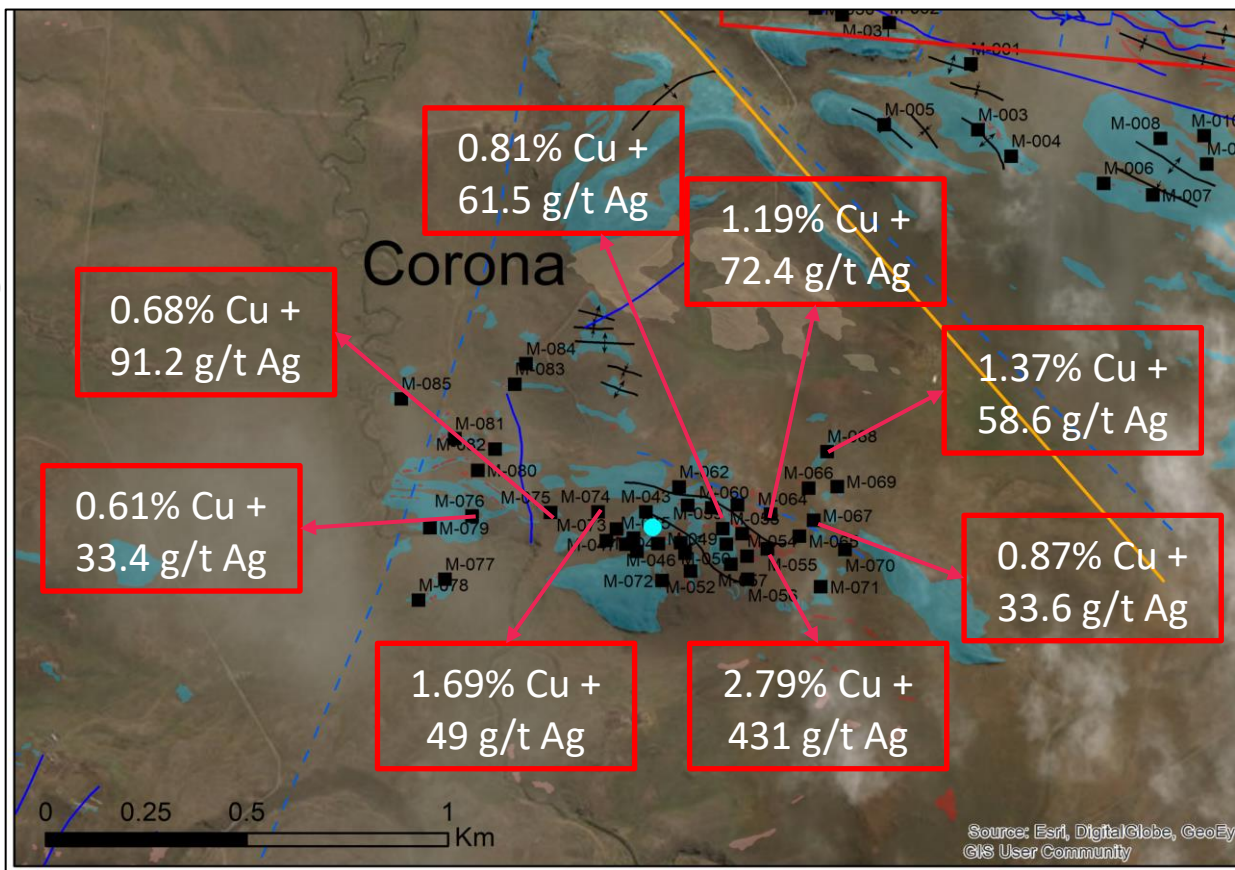

Corona is a target approximately 1,500 metres from Berenguela central, separated by the Ocuvi Fault. Corona shows significant outcropping rock formations with geological characteristics similar to Berenguela central, indicating the presence of a surficial, "Berenguela-style" deposit. A total of 42 rock chips were taken from the Corona area, with 13 returning values of  $\geq 0.50\%$  Cu, with multiple values above 1% and maximum copper values of 2.79% Cu. A total of 13 samples returned  $\geq 50$  g/t Ag with values as high as 431 g/t Ag. The Corona exploration area is approximately 1,500 metres from the borders of the Berenguela Central Deposit area. The current strike length is approximately 1,350 metres NW-SE and approximately 1,000 metres across North to South.

Berenguela & Corona Area Map

Outcropping Mineralisation at Corona

**Corona Historical Sampling:**

The areas in and around the Corona target were first sampled in 2009 by the previous operator, SSR Mining, followed by extensive magnetics and induce polarization surveys taken across the project

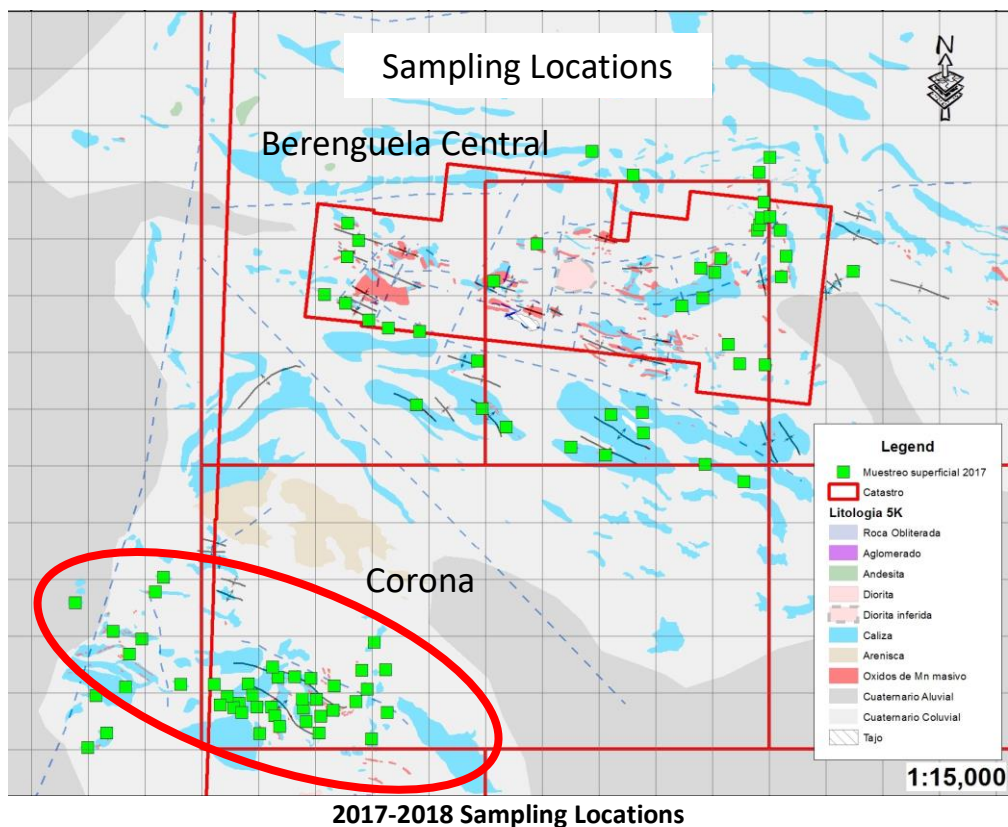

area. The 2009 sampling campaign identified outcropping mineralisation, indicating the presence of a large extension of the Berenguela deposit. A second field campaign was conducted in 2015 by SSR, further defining high grade copper and silver mineralisation at surface in the Corona area.

## Geophysics

In 2015, SSR conducted Induced Polarisation (IP) and magnetic surveys to supplement the 2009 ground survey and the 2010 Magneto-Telluric (MT) work that was done throughout the Berenguela Property. The IP and magnetic surveys identified chargeability anomalies that are localised within the Corona boundaries and are interpreted to represent continuation of the Berenguela Central deposit and potentially another style of mineralisation. The chargeability anomalies within the Corona area occur from surface to 100 metres of depth and the intensity of these signals is very similar to the Berenguela Central deposit. The targets of upcoming drilling campaigns will be driven by locations of these anomalies characterised by polymetallic veins and disseminations that contain lead, zinc, and copper sulfide minerals.

Geophysics Map of Berenguela & Corona

## Next Steps

VAL is currently conducting a detailed field mapping exercise at Corona, as well as additional surface sampling to further define drill targets at Corona for the 2018 drill program. VAL expects to complete the additional sampling and design of the drill program in the coming 4-6 weeks. The Company will aim to commence drilling in April or May of 2018.

### **Competent Persons Statement**

The technical information in this release is based on compiled and reviewed data by Mr. Marcelo Batelochi. Mr. Batelochi is an independent consultant with MB Geologia Ltda and is a Chartered Member of AusIMM – The Minerals Institute. Mr. Batelochi has sufficient experience which is relevant to the style of mineralization and type of deposit under consideration and to the activity which is being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Mr. Batelochi consents to the inclusion in the report of the matters based on their information in the form and context in which it appears. Mr. Batelochi accepts responsibility for the accuracy of the statements disclosed in this release.

None of their personnel helped with the sampling however they would assist SSR samplers at times</li> </ul>
<b>Drill sample recovery</b>	<ul style="list-style-type: none"> <li>• <i>Method of recording and assessing core and chip sample recoveries and results assessed.</i></li> <li>• <i>Measures taken to maximise sample recovery and ensure representative nature of the samples.</i></li> <li>• <i>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</i></li> </ul>	<ul style="list-style-type: none"> <li>• Drilling conditions ranged from difficult to good. Drilling through dry highly manganese replaced limestone was good however clay altered carbonates when wet posed difficult drilling conditions. Where the rock was dry typically in the upper 20-50 meters drilling conditions were good and drilling was done without water. When the rock was wet at depth and clay zones were encountered drilling conditions were difficult. When these conditions were encountered the drillers had to inject water along with additives.</li> <li>• During the first part of the first drilling program the drillers had numerous lost intervals. They learned how to drill the property by the end of the first program increasing recoveries and improving penetration rates. They learned that by using additives along with water and a face sampling hammer clay zones could be drilled while still recovering sample. A typical reason why there were zones with no recovery was that clay would clog the hammer and or tubes and the drillers would continue to drill. This usually occurred on night shift when the driller didn't want to take the time to check either the drill rods, tubes leading to the cyclone or the hammer. During the second program when it appeared that there might be clogging they immediately switched to water injection.</li> <li>• In the RC drilling campaign 2017 the number of lost intervals was very small.</li> </ul>

TABLE 1 – Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section)

Note: Information from NI-43101 report performed by James A. McCrea, audited and revised by Marcelo A. Batelochi (MAusimm – CP)

Criteria	JORC Code explanation	Commentary
<b>Mineral tenement and land tenure status</b>	<ul style="list-style-type: none"> <li>Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.</li> <li>The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</li> </ul>	<ul style="list-style-type: none"> <li>The Berenguela Property encompasses approximately 141.33 hectares situated in the eastern part of the Western Cordillera of south-central Peru and consists of two mineral concessions. The Berenguela concessions are located within the Department of Puno and lie within Peruvian National Topographic System (NTS) map area Lagunillas, No. 32-U. The centre of the Berenguela concessions is at 15° 40' South Latitude and 70° 34' West Longitude</li> </ul>
<b>Exploration done by other parties</b>	<ul style="list-style-type: none"> <li>Acknowledgment and appraisal of exploration by other parties.</li> </ul>	<ul style="list-style-type: none"> <li>In March of 2004, SSR entered into an option agreement with SOMINBESA (KCA) to purchase 100% of the silver resources contained in the Berenguela Project. SSR completed the exploration drill program in July of 2005 after completing 222 reverse circulation drill holes.</li> <li>In 2017 SSR agrees to a sale of the Berenguela deposit to Valor Resources, under terms disclosed to the market in February 2017.</li> </ul>
<b>Geology</b>	<ul style="list-style-type: none"> <li>Deposit type, geological setting and style of mineralisation.</li> </ul>	<ul style="list-style-type: none"> <li>Based on the distribution and form of the potentially economic bodies of Mn-Cu-Ag-Zn mineralization within the structurally deformed limestone formation there is little doubt that Berenguela represents a type of epigenetic, replacement-type ore deposit (Clark et al., 1990). Silver- and copper-mineralized veins of quartz and/or carbonate appear to be a very minor component of the deposit. What is debateable at Berenguela is whether or not, or to what extent supergene processes played a role in the formation of the deposit.</li> <li>More specifically, is the extensive development of manganese oxides the result of the surface oxidation of hypogene manganiferous carbonates (manganocalcite and/or rhodochrosite) which had replaced calcite and dolomite adjacent to fractures in the precursor limestone and where silver, copper and zinc were deposited as sulphides synchronous with or subsequent to the Mn-carbonate replacement</li> </ul>
