ASX:SVM

DISCOVERY OF SIGNIFICANT NEW ZONE OF SAPROLITE-HOSTED GRAPHITE ALONG STRIKE FROM MALINGUNDE

Sovereign Metals Limited ("the Company" or "Sovereign") is pleased to report the third batch of assay results from the 2017 aircore drilling program completed on its 100%-owned saprolite-hosted flake graphite projects in Malawi. The results represent drilling on a new zone of saprolite-hosted graphite mineralisation at Msinja, 1.5km to the south-east of the southern-most part of the main Malingunde deposit.

Aircore drilling at Malingunde, and other regional targets was conducted in late 2017, with 210 holes for 6,212 metres completed. The drilling program was designed to further define and upgrade the JORC resource classification levels for inclusion in the Malingunde Pre-feasibility Study, as well as to test graphite mineralisation at Msinja and other targets at Lifidzi, some 35km to the south-east.

The drilling at Msinja has defined a new and significant zone of high-grade saprolite-hosted graphite mineralisation over approximately 1km of strike. The mineralisation at Msinja will potentially add significantly to the overall resource base. The Company is targeting an updated JORC resource estimate to be delivered in Q2 2018.

HIGHLIGHTS:

Assays for the third batch of 2017 aircore samples (34 of 210 holes, with 104 previously reported) have been received, with the majority of results reported from the Msinja target.

The drilling at Msinja has defined high-grade zones of saprolite-hosted flake graphite mineralisation over about 1km of strike, which remains open to the south-east. Results include:

MGAC0349: 18m @ 9.1% TGC inc. 5m @ 12.0% TGC

MGAC0352: 15m @ 15.1% TGC inc. 5m @ 21.3% TGC

MGAC0366: 10m @ 16.7% TGC inc. 5m @ 20.2% TGC

Results for the final 72 remaining aircore holes, from the central and northern parts of Malingunde Main Zone, are expected to be delivered over the coming weeks, and will be provided to the market when received.

An additional, large Exclusive Prospecting Licence (EPL0492) of 1,896km², located to the north of Malingunde and covering ground highly prospective for saprolite-hosted graphite deposits, has been granted to Sovereign by the Malawi Government. Sovereign continues to expand on its first mover advantage in the region, with the Company currently holding 3,993km² in central Malawi.

Sovereign's Managing Director Dr Julian Stephens commented, "The new graphite zone at Msinja is a fantastic discovery for Sovereign as it demonstrates high-grade, saprolite hosted graphite mineralisation is developed over a strike length in excess of 7km. This gives us further confidence that we will grow the global resource by discovery of additional new deposits to support a multi-generational graphite mining centre, with one of the lowest cost production profiles globally."

19 March 2018

Msinja aircore drilling results

The 2017 drilling program at Malingunde and other regional targets comprised a total of 210 aircore holes for 6,212 metres of drilling. Results for the first 104 aircore holes which focused on infill of the Malingunde Main Deposit were reported on 17th January and 20th February. Results for a total 34 holes (28 from Msinja and 6 from regional targets at Lifidzi) are covered in this report. Results for a further 72 holes from the Malingunde Main Deposit are pending and will be reported once received. The Company expects an updated JORC resource estimate incorporating the new drilling results will be delivered in Q2 2018.

The results from the 28 holes drilled at Msinja show wide (up to 100m cumulative surface widths) and high-grade zones of saprolite-hosted flake graphite mineralisation over about 1km of strike which is open to the south-east. Additionally, the drilling at Msinja has highlighted a number of very high-grade zones of circa 12% to 20% TGC.

This new discovery is significant, as given Msinja's very close proximity to Malingunde (1.5km to the south east), additional tonnages of high-grade saprolite mineralisation have the potential to increase overall mine life and/or provide additional optionality for the mining schedule.

Selected results from the 28 aircore holes from Msinja reported are listed below, with full results listed in Table A.

MGAC0342: 25m @ 7.3% TGC

• MGAC0349*: 18m @ 9.1% TGC inc. 5m @ 12.0% TGC

• MGAC0352*: 15m @ 15.1% TGC inc. 5m @ 21.3% TGC

• MGAC0353: 15m @ 7.9% TGC inc. 6m @ 10.4% TGC

MGAC0366*: 10m @ 16.7% TGC inc. 5m @ 20.2% TGC

^{*}denotes results that are also reported in highlights on front page

Figure 2. Map showing recently received aircore drilling results and mineralisation at the new Msinja discovery.

Lifidzi aircore drilling results

A total of 21 aircore holes were planned to test regional targets previously identified by hand-auger drilling at Lifidzi, some 35km south east of Malingunde. The onset of the wet season in mid December 2017 forced the early curtailment of this program, with only 6 holes having been completed on two targets, Chiziro and Thete. The Company plans to complete this regional program in Q3 2018.

Whilst only 6 holes were completed, they highlight that high-grade, saprolite hosted graphite mineralisation occurs at both prospects and warrants further drilling.

Best results from the limited program are listed below, with full results shown in Table A.

LFAC0002: 23m @ 6.7% TGC inc. 6m @ 9.1% (Chiziro prospect)

• LFAC0006: 12m @ 8.0% TGC (Thete prospect)

19 March 2018

Signficant additions to Malawi land-holding

An additional, large Exclusive Prospecting Licence EPL0492 of 1,895km², located to the north of Malingunde and covering ground highly prospective for saprolite-hosted graphite deposits, has been granted to Sovereign by the Malawi Government. With other statutory relinquishments, this brings the Company's total land holding in central Malawi up to 3,993km².

The Company intends to re-commence regional exploration for further high-grade, saprolite-hosted graphite mineralisation on EPL0492 and its other existing EPLs in Q2 2018.

Competent Person Statement

The information in this report that relates to Exploration Results is based on information compiled by Dr Julian Stephens, a Competent Person who is a member of the Australian Institute of Geoscientists (AIG). Dr Stephens is the Managing Director of Sovereign Metals Limited and a holder of shares, options and performance rights in Sovereign Metals Limited. Dr Stephens has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken, to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Dr Stephens consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

Forward Looking Statement

This release may include forward-looking statements, which may be identified by words such as "expects", "anticipates", "believes", "projects", "plans", and similar expressions. These forward-looking statements are based on Sovereign's expectations and beliefs concerning future events. Forward looking statements are necessarily subject to risks, uncertainties and other factors, many of which are outside the control of Sovereign, which could cause actual results to differ materially from such statements. There can be no assurance that forward-looking statements will prove to be correct. Sovereign makes no undertaking to subsequently update or revise the forward-looking statements made in this release, to reflect the circumstances or events after the date of that release.

Appendix 2: JORC Code, 2012 Edition - Table 1

Section 1 Sampling Techniques and Data

Jechniques	Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc.). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.	The aircore drilling method was employed to obtain bulk drill cuttings at nominal 1-metre (downhole) intervals from surface. All 1-metre samples were collected in plastic bags directly beneath the drilling rig cyclone underflow. The entire 1-metre sample was manually split using either a 3-tier (87.5:12.5 split) or single tier (50:50 spli riffle splitter or a combination thereof to facilitate the mass reduction of a laboratory assay split. Compositing of the laboratory sample split was performed on a geological basis. Mineralised (>=3% v/v visual) laboratory splits of 1-metre intervals from surface to the top of the saprolite zone were not composited whereas mineralised splits of the underlying saprolite and saprock intervals were composited nominally at 2-metres. Unmineralised (=<3% v/v visual), laboratory splits of 4-metre intervals from top of hole to bottom of hole were composited. Laboratory splits were submitted Intertek Perth for assay sample preparation. Total Graphitic Carbon (TGC analysis of all assay pulps samples was undertaken by Intertek Perth. Drilling and sampling activities were supervised by a suitably qualified Company geologist who was presen at the drill rig at all times. All bulk 1-metre drill samples were geologically logged by the geologist at the drill site. All 1-metre downhole drill samples collected in plastic bags from directly beneath the cyclone underflow were individually weighed and moisture content was qualitatively logged prior to further splitting and

Sub-sampling	If core, whether cut or sawn and whether	No core was drilled during this program
techniques	quarter, half or all core taken.	
and sample preparation	If non-core, whether riffled, tube sampled, rotary split, etc. and whether sampled wet or dry.	The entire 1-metre sample was manually split using either a 3-tier (87.5:12.5 split) or single tier (50:50 split) riffle splitter or a combination thereof to facilitate the mass reduction of a laboratory assay split. Compositing of the laboratory sample split was performed on a geological basis. Mineralised (>=3% v/v visual) laboratory splits of 1-metre intervals from surface to the top of the saprolite zone were not composited whereas mineralised splits of the underlying saprolite and saprock intervals were composited nominally at 2-metres. Unmineralised (<=3% v/v visual), laboratory splits of 4-metre intervals from top of hole to bottom of hole were composited. All wet samples were removed from the drill site without splitting and relocated to the Company's premises in Lilongwe. The wet samples were transferred into large metal trays and sun dried. Samples were subsequently hand pulverised and thoroughly homogenised prior to splitting 50:50 with a single tier riffle splitter. One of the off-splits was submitted to the laboratory for assay. All rejects splits (i.e. the material not sent for assaying) of each individual 1-metre interval were returned to original sample bag, cable tied and placed in storage for future reference.
	For all sample types, the nature, quality and appropriateness of the sample preparation technique.	Sample preparation is conducted at either Intertek in Perth or Johannesburg. The entire submitted sample (=< ~3kg) is pulverised to 85% -75µm in a LM5. Approximately 100g pulp is collected and sent to Intertek-Genalysis Perth for chemical analysis.
	Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.	All sampling was carefully supervised. Ticket books were used with pre-numbered tickets placed in the laboratory sample bag and double checked against the sample register. Subsequent to splitting an aluminium tag inscribed with hole id/sample interval was placed inside the bulk 1-metre sample bag. Field QC procedures involve the use of certified reference material assay standards, blanks, duplicates, replicates for company QC measures, and laboratory standards, replicate assaying and barren washes for laboratory QC measures. The insertion rate of each of these averaged better than 1 in 20.
	Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.	A program of field replicate splitting of selected (5%) mineralised intervals was completed at the conclusion of the drill program. In addition, a number of air core holes have been drilled to "twin" diamond holes, to assess the representivity of the air drilling. The results of these programs will be assessed when results are received.
	Whether sample sizes are appropriate to the grain size of the material being sampled.	All mass reduction of aircore drill samples undertaken during field sampling and laboratory sample preparation were guided by standard sampling nomograms and fall within Gy's safety limits for the type of mineralisation sampled.
Quality of assay data and laboratory tests	The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.	The assaying and laboratory procedures are considered to be appropriate for reporting graphite mineralisation, according to industry best practice. Each entire sample was pulverised to 85% -75µm. Approximately 100g pulp is collected for analysis at Intertek-Genalysis Perth. A sample of 0.2g is removed from the 100-gram pulp, first digested in HCl to remove carbon attributed to carbonate, and is then heated to 450°C to remove any organic carbon. An Eltra CS-2000 induction furnace infra-red CS analyser is then used to determine the remaining carbon which is reported as Total Graphitic Carbon (TGC) as a percentage.
	For geophysical tools, spectrometers, handheld XRF instruments, etc., the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.	No non-laboratory devices were used for chemical analysis.
	Nature of quality control procedures adopted (e.g. standards, blanks, duplicate, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.	Field QC procedures involve the use of certified reference material assay standards, blanks, duplicates and replicates for company QC measures, and laboratory standards, replicate assaying and barren washes for laboratory QC measures. The insertion rate of each of these averaged better than 1 in 20.
Verification of sampling & assaying	The verification of significant intersections by either independent or alternative company personnel.	Significant mineralisation intersections were verified by alternative company personnel. An independent resource consultant conducted a site visit during December 2016 during the aircore drilling program. All drilling and sampling procedures were observed by the consultant during the site visit. These procedures remained in use for this drilling program.
	The use of twinned holes. Documentation of primary data, data entry	Several of the 2016 PQ diamond core holes were twinned by aircore holes to assess sampling representivity. All data is initially collected on paper logging sheets and codified to the Company's templates. This data
	procedures, data verification, data storage (physical and electronic) protocols.	was hand entered to spreadsheets and validated by Company geologists. This data was then imported to a Microsoft Access Database then validated automatically and manually. Assay data is provided as .csv files from the laboratory and loaded into the project specific drill hole database. Spot checks are made against the laboratory certificates.
Location of data points	Discuss any adjustment to assay data. Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.	No adjustments have been made to assay data. Collar points were set out using the Company's R2 Rover DGPS (accuracy 0.04m x/y), and upon completion of drilling all collars were picked-up again using the same survey tool. The accuracy of R2 Rover unit is quoted to be 0.04m x/y and 0.09m z. Down-hole surveying was undertaken on selected holes to determine drill hole deviation. Surveys were carried out using a Reflex Ez-Trak multi-shot survey tool at nominal 30m intervals down hole on selected holes was used to show that significant deviation does not occur over the relatively short length of the aircore holes. As such drill hole deviation is not considered material throughout the program.
	Specification of the grid system used. Quality and adequacy of topographic control.	WGS84 (GRS80) UTM Zone 36 South The Company's DGPS survey tool has sub 0.1m accuracy in the X, Y and Z planes. This is considered sufficiently accurate for the purposes of topographic control. In addition, the Company has installed several independently surveyed control pegs and undertakes QC surveys on these points before every survey program. Given the low topographic relief of the area it is believed that this represents high quality control. Previous checking of Hand Auger holes with the Shuttle Radar Topographic Mission (SRTM) 1-arc second digital elevation data has shown that the Leica GPS System produces consistently accurate results.

Section 2 Reporting of Exploration Results

Criteria	JORC Code explanation	Commentary
Mineral tenement & land tenure status	Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environment settings. The security of the tenure held at the time of reporting along with any known	The Company owns 100% of 4 Exclusive Prospecting Licences (EPLs) in Malawi. EPL0355 renewed in 2017 for 2 years, EPL0372 renewed in 2018 for 2 years and EPL0413 renewed in 2017 for 2 years. EPL0492 was granted in 2018 for an initial period of three years (renewable). The tenements are in good standing and no known impediments to exploration or mining exist.
	impediments to obtaining a licence to operate in the area.	
Exploration done by other parties	Acknowledgement and appraisal of exploration by other parties.	No other parties were involved in exploration.
Geology	Deposit type, geological setting and style of mineralisation	The graphite mineralisation occurs as multiple bands of graphite gneisses, hosted within a broader Proterozoic paragneiss package. In the Malingunde and Lifidzi areas specifically, a deep tropical weathering profile is preserved, resulting in significant vertical thicknesses from near surface of saprolite-hosted graphite mineralisation.
Drill hole information	A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes: easting and northings of the drill hole collar; elevation or RL (Reduced Level-elevation above sea level in metres of the drill hole collar); dip and azimuth of the hole; down hole length and interception depth; and hole length	Refer to Tables A and B in Appendix.
	If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case	Not applicable, no information has been excluded.
	In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high-grades) and cut-off grades are usually Material and should be stated.	All sample assays contribute to significant intercepts, while adhering to a minimum total significant intercept grade of >=5%. For simplification of reporting following positive metallurgical results in the treatment of pedolith material, all material above the saprolite-saprock boundary is considered as saprolite during generation of significant intercepts.
Data aggregation methods	Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.	Significant intercepts were calculated using an outer (edge) sample lower cut-off grade of >=5% TGC, minimum intercept width of 3m, and a maximum of 6m internal dilution where the final intercept averages >=5% TGC. Substantial higher grade zones are reported as separate "including" intercepts within Table B.
	The assumptions used for any reporting of metal equivalent values should be clearly stated.	No metal equivalent values are used in this report.

Criteria	JORC Code explanation	Commentary
	These relationships are particularly important in the reporting of Exploration Results.	Preliminary interpretation of mineralised zones in aircore holes supported by DD (2016) orientated core measurements suggests that mineralised zones are shallow-moderate east dipping.
Relationship between mineralisatio widths & intercept	If the geometry of the mineralisation with	Flake graphite mineralisation is conformable with the main primary layering of the gneissic and schistose host lithologies. Drill hole inclination of -60 degrees are generally near orthogonal to the regional dip of the host units and dominant foliation and hence specific drill hole intercepts for -60 degree holes may only approximate true width. The averaged strike of mineralised zones is approximately 160° grid whereas all -60 inclined aircore holes were orientated at grid east.
lengths	If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known'.	Not Applicable, refer to explanation directly above.
Diagrams	Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of the drill collar locations and appropriate sectional views.	See Figures 1 and 2 within the main text of this report.
Balanced reporting	Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high-grades and/or widths should be practiced to avoid misleading reporting of exploration results.	Representative reporting of low and high-grades has been effected within this report.
Other substantive exploration data	Other exploration data, if meaningful and material, should be reported including (but not limited to: geological observations; geophysical survey results; geochemical survey results; bulk samples - size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	No additional meaningful and material exploration data has been excluded from this report that has not previously been reported to the ASX.
	The nature and scale of planned further work (e.g. test for lateral extensions or depth extensions or large-scale step-out drilling).	The next phase of exploration is to complete aircore drilling on regional saprolite targets identified through hand auger drilling.
Further work	Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.	See Figure 2 within the main text of this report.
